

# *Object Oriented Design and Analysis*

## *CPE 372*

### Lecture 11

### Refactoring

*Dr. Sally E. Goldin  
Department of Computer Engineering  
King Mongkut's University of Technology Thonburi  
Bangkok, Thailand*

# Why Design?

Find problems and resolve issues as early as possible in the development process

# Want to design systems with:

## High cohesion within modules

Each module has a limited number of clearly defined functional responsibilities

## Low coupling between modules

Communication and dependencies between modules are minimized to the greatest extent possible

*Software with these characteristics will be easier to build, understand, reuse, extend and change*

# Over time, software rots!

Software changes or extensions *reduce cohesion*, introduce *undesirable dependencies*, and *muddy the distinctions* in the original design.

# Dependency Graph of Mature Software

From: <http://www.designsmells.com/articles/does-your-architecture-smell/>

THE LIFE OF A SOFTWARE  
ENGINEER.

CLEAN SLATE. SOLID  
FOUNDATIONS. THIS TIME  
I WILL BUILD THINGS THE  
RIGHT WAY.

MUCH LATER...

OH MY. I'VE  
DONE IT AGAIN,  
HAVEN'T I ?

# Refactoring can help

What is *refactoring*?

*Changing the design of existing code  
without modifying its behavior*

# Refactoring can occur at many levels

## Method level

- Splitting overly long methods
- Extracting common code into new methods
- Eliminating redundant code
- Increasing consistency in code structure

```
public abstract class AbstractCollection implements Collection {  
    public void addAll(AbstractCollection c) {  
        if (c instanceof Set) {  
            Set s = (Set)c;  
            for (int i=0; i < s.size(); i++) {  
                if (!contains(s.getElementAt(i))) {  
                    add(s.getElementAt(i));  
                }  
            }  
        }  
        else if (c instanceof List) {  
            List l = (List)c;  
            for (int i=0; i < l.size(); i++) {  
                if (!contains(l.get(i))) {  
                    add(l.get(i));  
                }  
            }  
        }  
        else if (c instanceof Map) {  
            Map m = (Map)c;  
            for (int i=0; i<m.size(); i++)  
                add(m.keys[i], m.values[i]);  
        }  
    }  
}
```

The diagram illustrates a Java method `addAll` in the `AbstractCollection` class. The method is annotated with several labels and lines pointing to specific code segments:

- Duplicated Code** (blue text): Points to the `if (!contains(s.getElementAt(i)))` condition in the `Set` branch.
- Duplicated Code** (purple text): Points to the `if (!contains(l.get(i)))` condition in the `List` branch.
- Alternative Classes with Different Interfaces** (green text): Points to the `if (!contains(s.getElementAt(i)))` and `if (!contains(l.get(i)))` conditions.
- Switch Statement** (red text): Points to the `if-else if-else if` structure.
- Inappropriate Intimacy** (red text): Points to the `m.keys[i]` and `m.values[i]` access in the `Map` branch.
- Long Method** (black text): Points to the entire `addAll` method.

## ***Class level***

- Splitting class functionality into multiple classes
- Extracting common functionality into a superclass
- Pushing functionality into subclasses
- Moving functionality from one class to another
- Adding new classes or interfaces to reduce dependencies (e.g. adapters, facades)

## ***Module/Package level***

- Moving some classes into a new package
- Creating a superclass or interface in one package to be implemented in another package

# *ShapeReader.java* (Exercise 4) – my first attempt

```
public AbstractShape readShape()
{
    AbstractShape newShape = null;
    boolean bError = false;
    String line;
    do
    {
        line = getNextLine();
        if (line != null)
        {
            String fields[] = line.split(" ");
            newShape = null;
            if (fields.length >= 4) /* should be at least four fields */
            {
                if (fields[0].equalsIgnoreCase("TRIANGLE"))
                {
                    if (fields.length == 7)
                        /* command plus 3 x,y points */
                    {
                        int[] x = new int[3];
                        int[] y = new int[3];
                        for (int i=0; i < 3; i++)
                        {
                            x[i] = convertToInt(fields[i*2+1]);
                            y[i] = convertToInt(fields[i*2+2]);
                            if ((x[i] < 0) || (y[i] < 0))
                            {
                                System.out.println("\t\tInvalid integer in triangle specification");
                            }
                        }
                        newShape = new Triangle(x[0],y[0],x[1],y[1],x[2],y[2]);
                    }
                }
                else if (fields[0].equalsIgnoreCase("SQUARE"))
                {
                    ....
                }
            }
        }
    }
}
```

# Refactored to shorten and reduce repetition

```
public AbstractShape readShape()
{
    AbstractShape newShape = null;
    boolean bError = false;
    String line;
    do
    {
        line = getNextLine();
        if (line != null)
        {
            newShape = parseCheckShapeCommand(line);
            if (newShape == null)
                System.out.println("\t\tBad line: '" + line + "' ==>
Skipping");
        }
    } while ((newShape == null) && (line != null));
    return newShape;
}
```

- 1) Pulled out all the code to check input and create shapes, and moved to **parseCheckCommand()**

# More method refactoring

```
private AbstractShape parseCheckShapeCommand(String line)
{
    AbstractShape newShape = null;
    String fields[] = line.split(" ");
    if (fields.length >= 4) /* should be at least four fields */
    {
        if (fields[0].equalsIgnoreCase("TRIANGLE"))
        {
            newShape = createTriangle(fields);
        }
        else if (fields[0].equalsIgnoreCase("SQUARE"))
        {
            newShape = createSquare(fields);
        }
        else if (fields[0].equalsIgnoreCase("DIAMOND"))
        {
            newShape = createDiamond(fields);
        }
        else if (fields[0].equalsIgnoreCase("CIRCLE"))
        {
            newShape = createCircle(fields);
        }
        else /* not a valid line */
        {
            System.out.println("\t\tInvalid shape command");
        }
    }
    else
    {
        System.out.println("\t\tLine has too few fields");
    }
    return newShape; /* could be null */
}
```

2) Separated the parsing from the shape creation

# Advantages of this refactoring

- ✓ Methods are much shorter, easier to understand
- ✓ Simple to add new shapes

**Compare the code** (in [\*demos/Lecture11\*](#)):

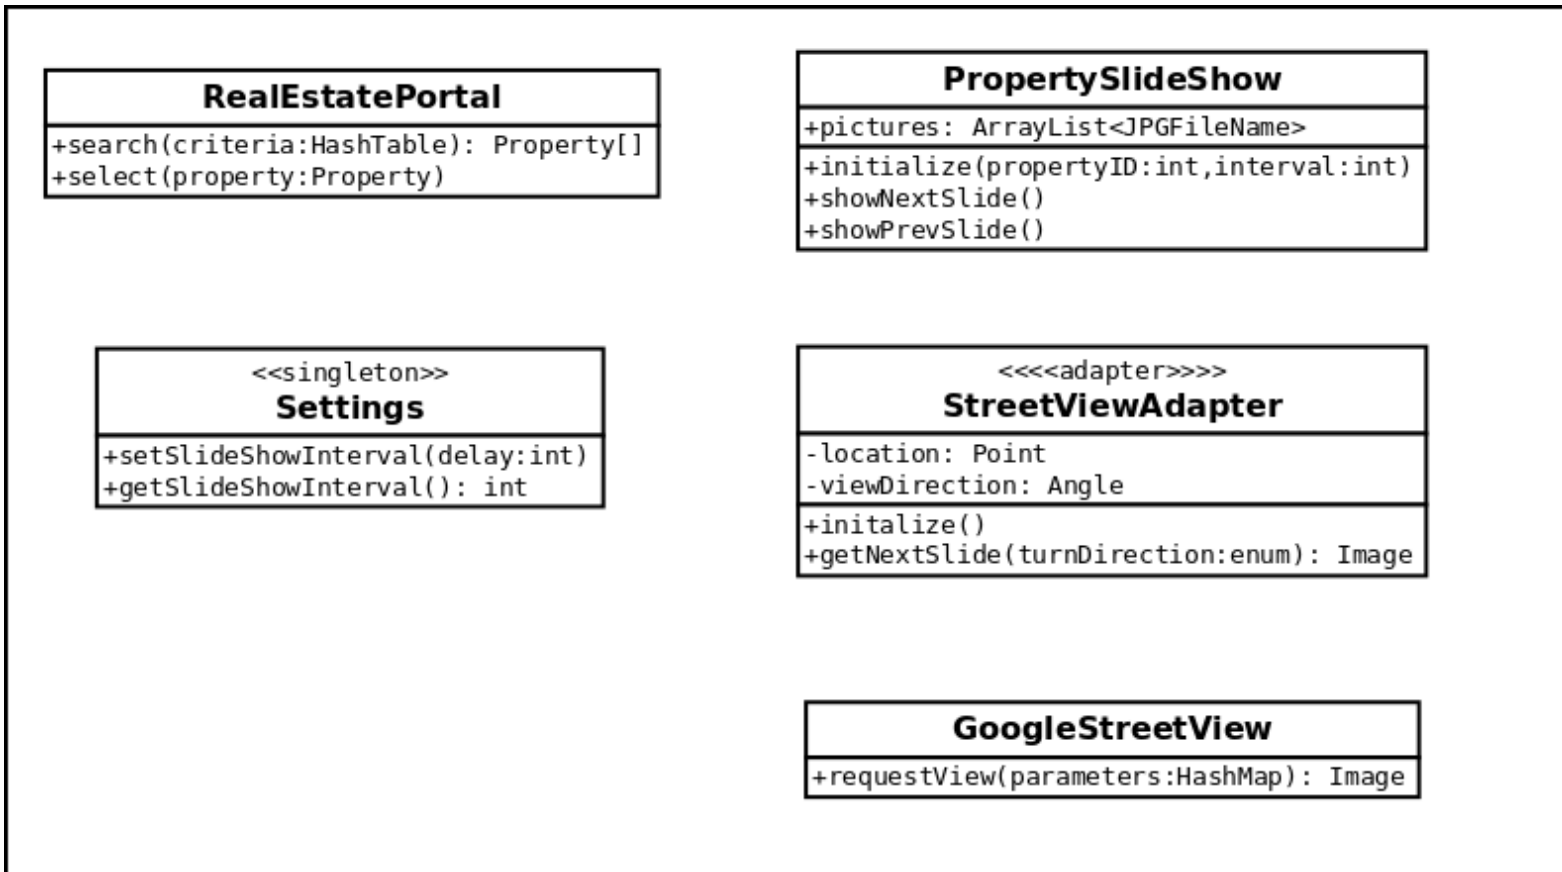

OriginalShapeReader.java

RefactoredShapeReader.java

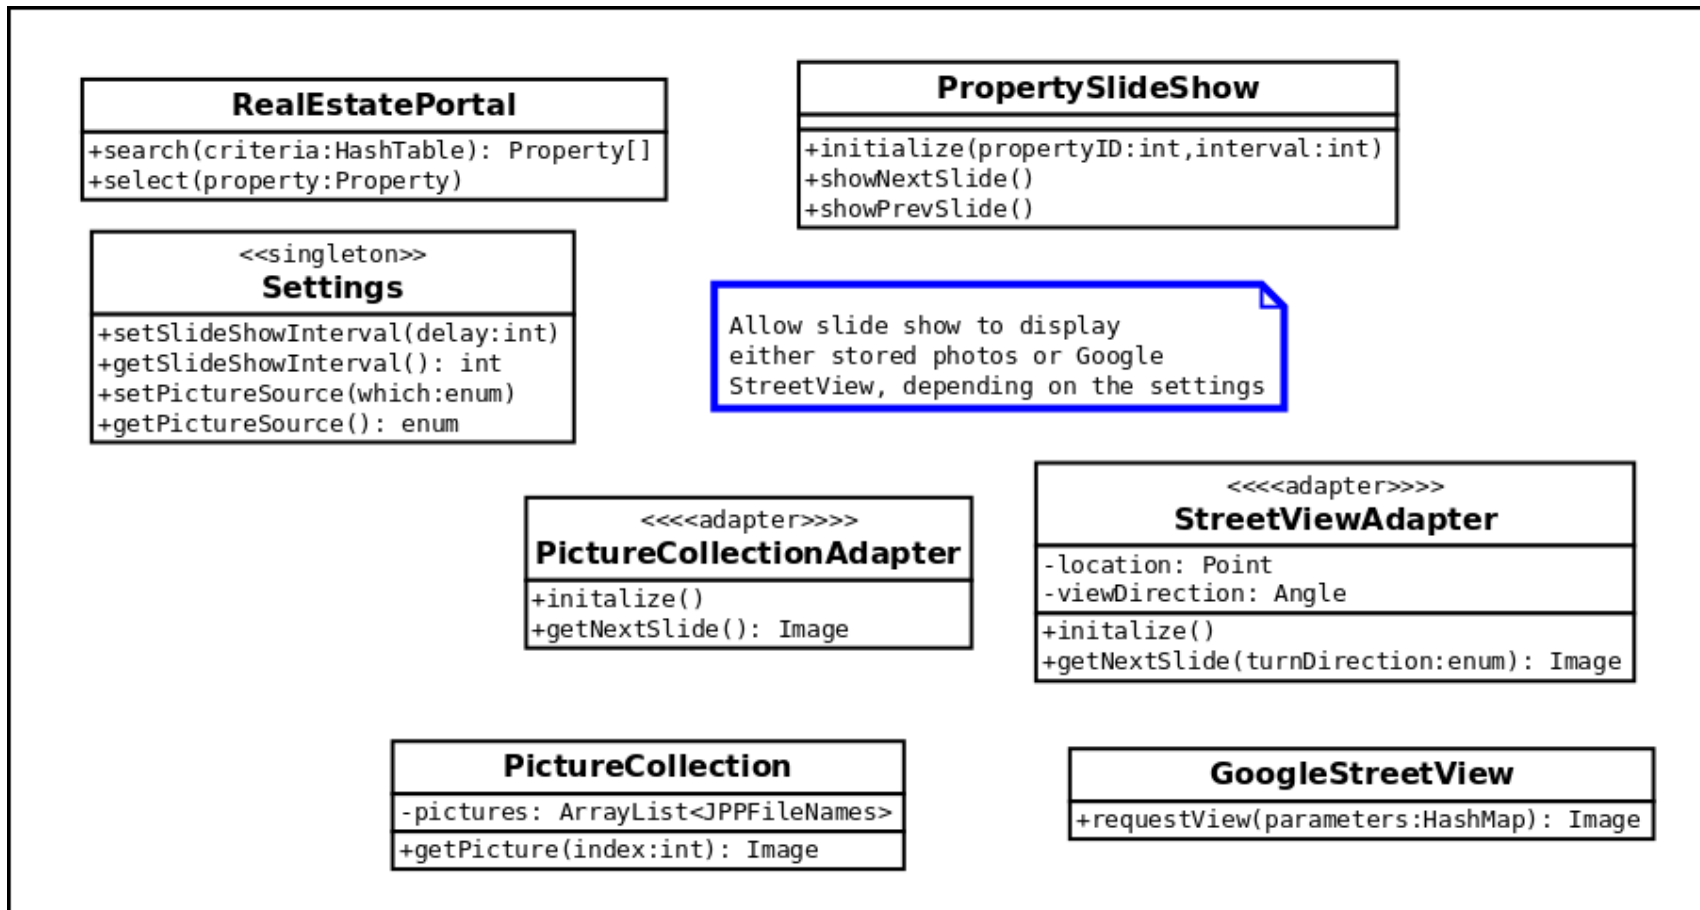

# Class Level Refactoring Example

This design has the undesirable feature that *PropertySlideShow* needs to do very different things depending on whether the source of the images is local photos or StreetView

# After Refactoring

We have split out the *PhotoCollection* class from *PropertySlideShow* and added an adapter for local image display that parallels the adapter class for StreetView

# How do you know that you need to refactor?

**Watch out for tell-tale problems:  
“code smells” and “design smells”**

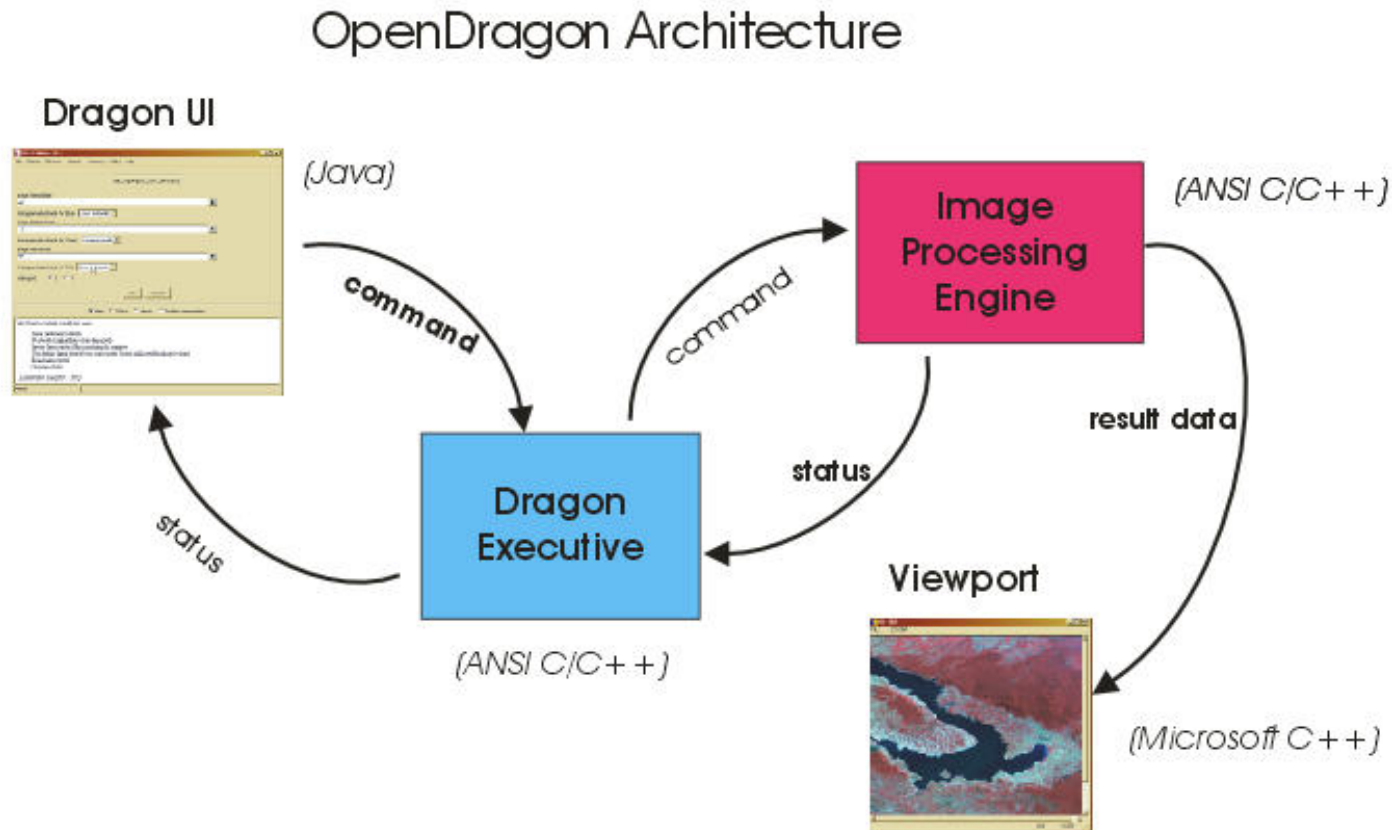

For a list of common “smells” see [https://en.wikipedia.org/wiki/Code\\_smell](https://en.wikipedia.org/wiki/Code_smell)

# Experience is the best teacher...

**So... we are going to do an exercise with a real software system that truly needs to be refactored!**

# OpenDragon Architecture

**Design and implementation of Java-based UI started in 2000, continued through 2006!**

**Less code rot than in some systems because only one developer (me!)**

# Design Goals

- ➔ **Instead of hard-coding the UI screens, develop a system that can generate the screens at run time based on a descriptive (XML) representation**
- ➔ **The entire UI must be internationalized**
- ➔ **UI generation system should be able to be applied to any application, not just OpenDragon**

# Demonstrations

- Overview of the source tree
- Building the XmlToUiBuilder test application
- Generating and displaying a user interface
- Exploring the XML descriptions

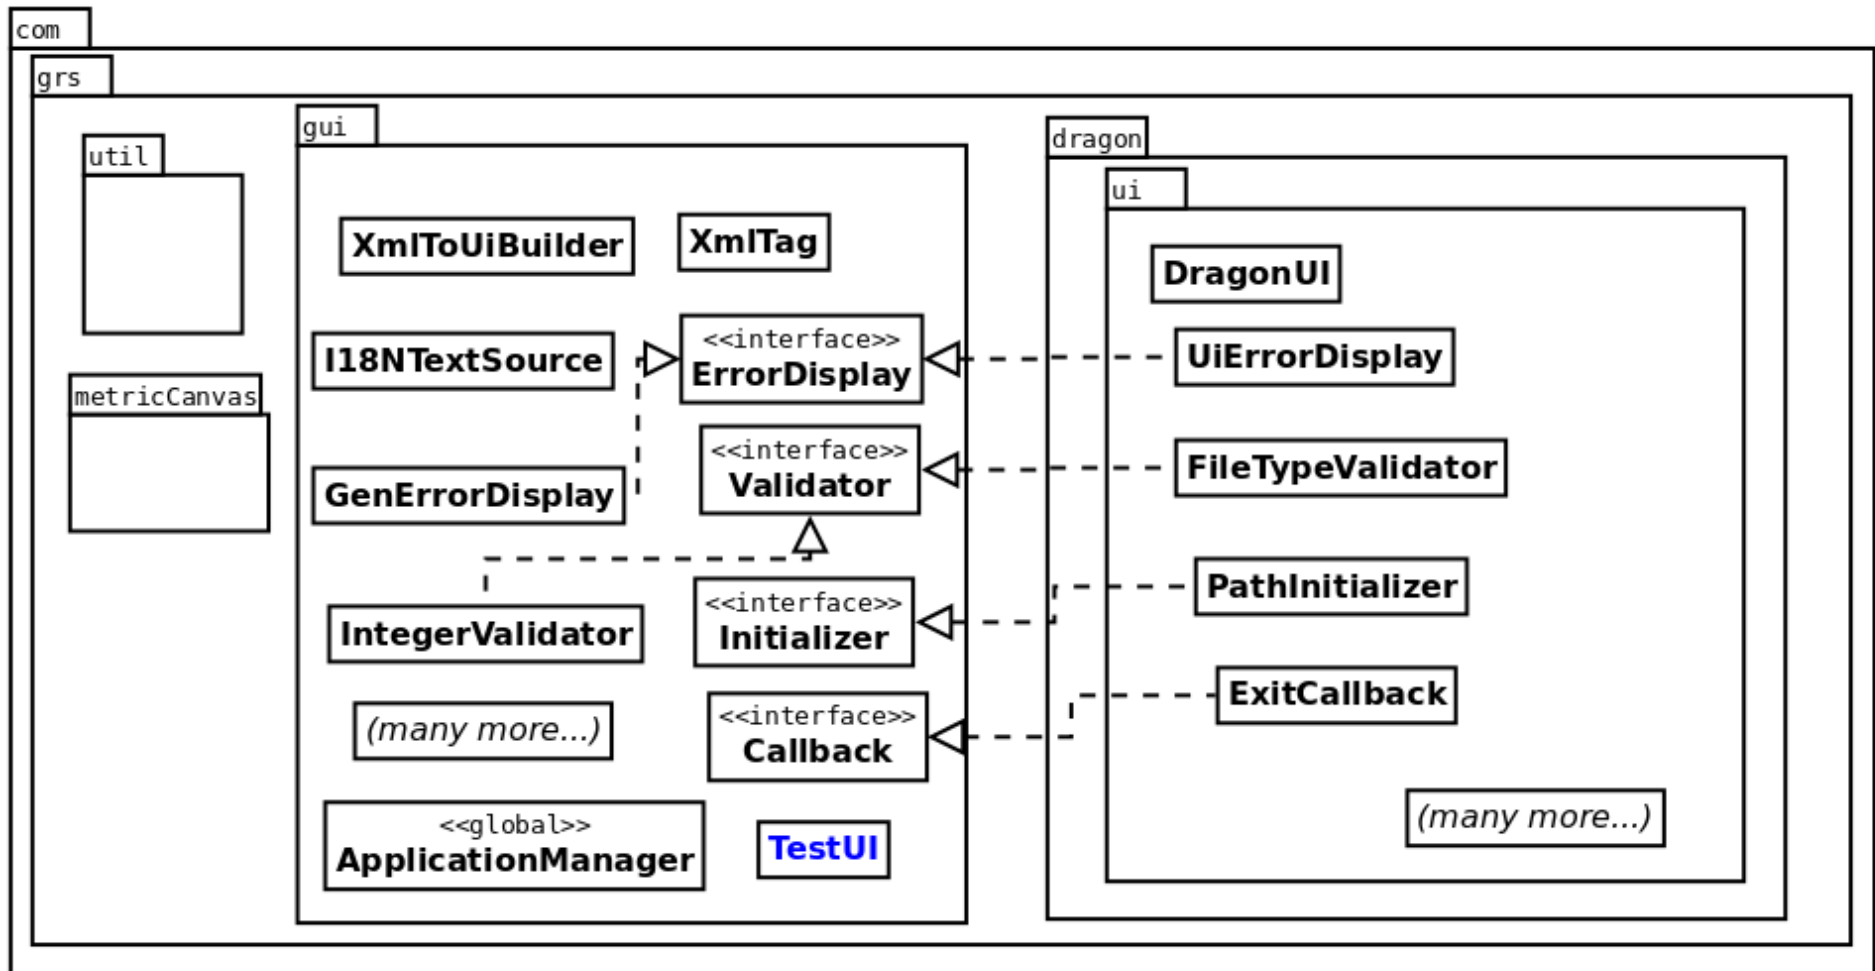

# Partial Package Diagram

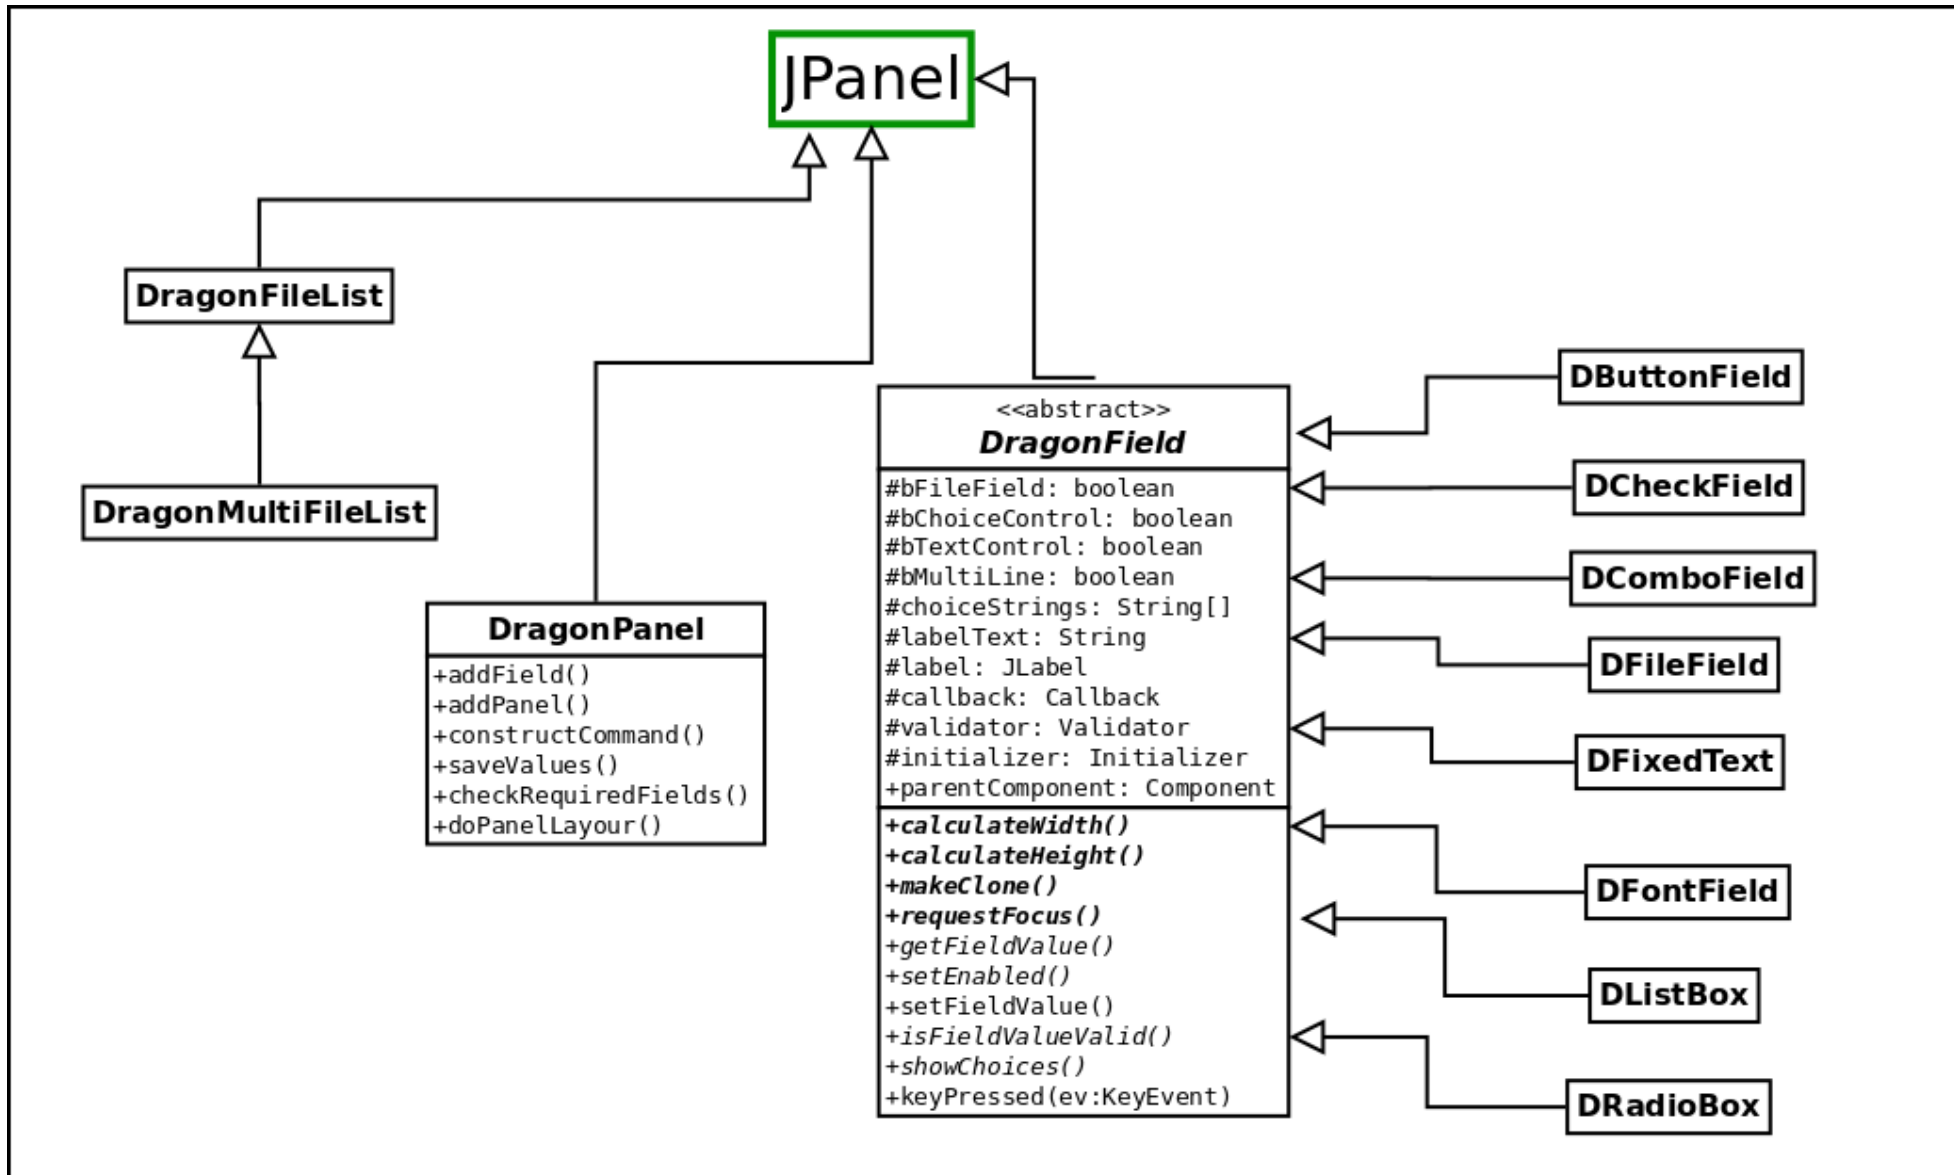

Package diagrams are a UML diagram type used to show the way classes are grouped and nested

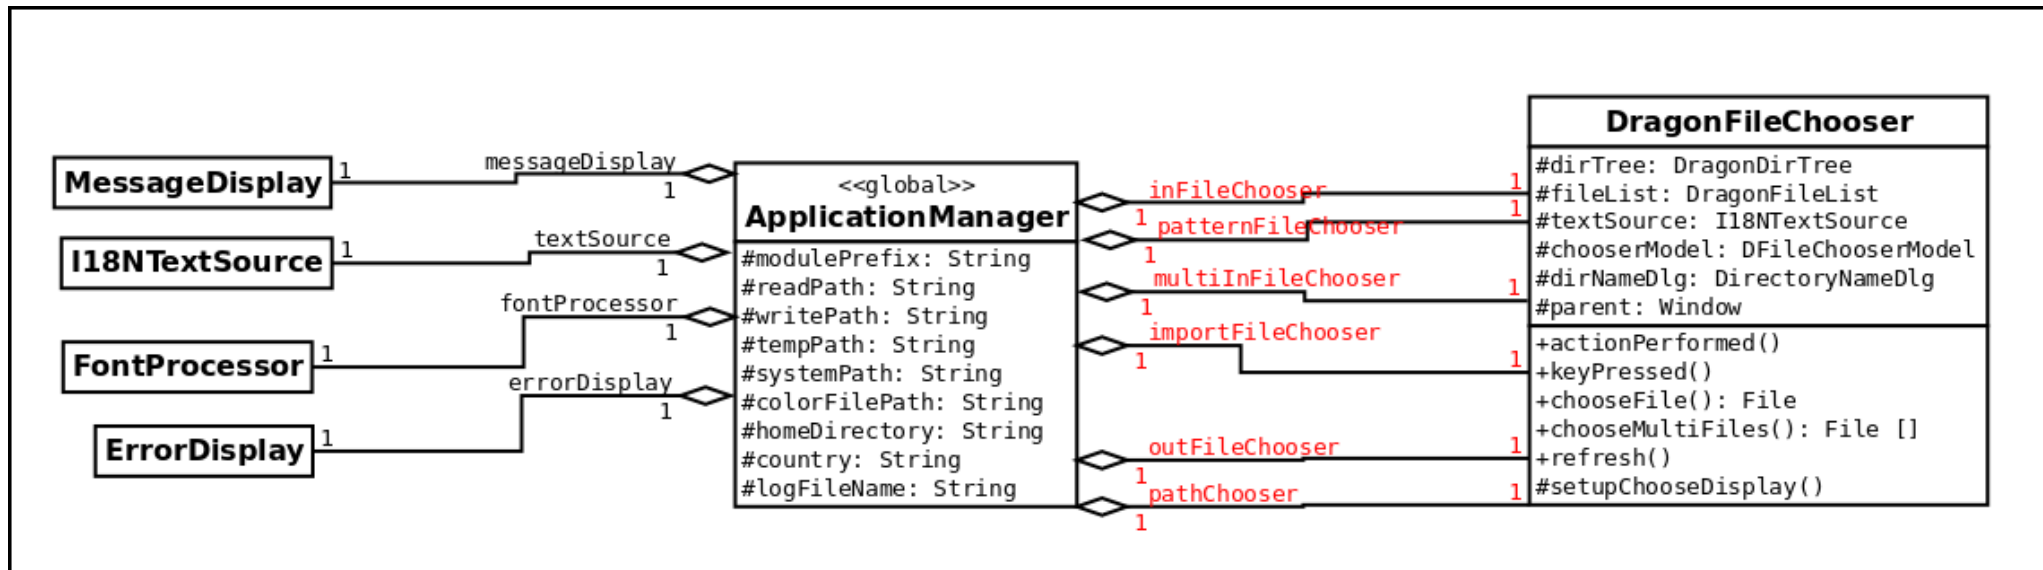

# Packages with Selected Classes

# Partial Class Diagram: UI Controls

# *ApplicationManager* has many dependencies

# What are the problems?

*The **XmlToUiBuilder** class is much too big – very difficult to understand and modify*

*The **XmlToUiBuilder** class incorporates too much Dragon-specific knowledge*

*The **ApplicationManager** class is a major “kludge”*

Global “catchall” class breaks encapsulation

Should not need to initialize the **ApplicationManager** in order to generate (any) UI

**We need to refactor!**

# Hands-on Exercise

Get together with your project team mate

Download the zip file **DragonExercise.zip** and unpack on your computer

Build and run the test version of ***XmlToUiBuilder*** using ***SimpleUi.xml***. (See the instructions document.)

Choose either ***XmlToUiBuilder.java*** or ***ApplicationManager.java***. Do you have any ideas how you could refactor the class to make it shorter, less complicated and/or have fewer dependencies?

Create a class diagram illustrating your ideas for refactoring

You will work for about an hour – then share your ideas with the rest of the class
